Abstract

The knowledge about medicinal plants coming from the traditional ethnobotanical culture is receiving a lot of scientific interest in these years, due to the low cost and the easier availability of herbs with respect to the common pharmaceutical products. In Cuba the use of herbs is very extended, because of the hard living conditions before the Revolution that forced the community to use internal resources, and because of the lack of drugs caused by the embargo. Just a few of the plants used by the traditional religious group of Cuba, the Santeria, have been scientifically investigated, even though many of them could be a vast reservoir of knowledge for future scientific research. In the taxonomy of these species, the correspondence between local name and scientific one is often mismatched and because of that the use of herbs is prone to errors. The experimental project was conducted through a preliminary bibliographic research, interviews and taxonomic control. A list of plants was obtained in which there is correspondence between local names and scientific ones and in which traditional and scientifically recognized uses are compared. The results show that ethnobotanical traditions in Cuba are still very used by the local communities, which demonstrate to have an extensive botanical knowledge in their culture, but there is the need to update and improve it. Only a small part of the herbs used in Cuba have been scientifically investigated; therefore, it is necessary to start further studies about the local flora, check the effective medicinal properties, find new bioactive compounds previously unknown to science. Our work has led to a review of the local names, in correspondence with the current systematic. We have also demonstrated the usefulness of keeping alive the traditional knowledge of indigenous communities.

Introduction

Knowledge related to medicinal plants is becoming increasingly important worldwide, due to the increasing attention to natural remedies in the Western world and due to the easy availability and the low cost in developing countries.

In Cuba, the use of herbs with magical or religious purposes is very widespread, as is the use of herbs with medical purposes, due to the hard living conditions and the embargo.

The medical use of plants has ancient origins: they come from the old indigenous populations of Cuba and, mostly, from slaves from African regions.

During our work in Cuba, the Santeria has proven to be a religion that prefers the traditional use of plants for ceremonies and remedies, even though only a few of them have been investigated in the scientific community. This lack of scientific information can cause misunderstanding in the use of herbs.

Therefore, we considered necessary a correction of the mismatched local names and a quest for correspondence with the scientific names as a beginning in the botanic scientific development.

Materials and methods

The project has been developed through a preliminary investigation on the existing religious literature, followed by individual and collective interviews, the botanical identification of the herbs and the comparison of local names with the scientific ones, researching the scientific literature.

The preliminary research on bibliography has been based on Lydia Cabrera's book "*El Monte*", verified through the integration with scientific literature, description in field of the plants listed in the book and the help of local botanists and taxonomists.

The interviews were carried out through participatory approach and involved 22 people, principally farmers and religious practitioners (photo 1, 2, 3); the spontaneous gathering of family, neighbors and curious persons, allowed, in fact, to interview a lot more people.

Photo 1 – Interviews to herbs expert (Foto Carlomagno).

Photo 2 – Interview to Practicantes of Santeria (Foto Carromagno).

Photo 3 – Offerings to Gods include medicinal plants and their products (Foto Contino).

The phase of taxonomic control was conducted through the identification of samples studied at the Research Station “Indio Hatuey” of the University of Matanzas, and some help from the Institute of Ecology and Systematics in Havana and in the School of Pharmacy of the Public Health Department of the University of Havana (Photo 4).

Photo 4 – Identification of plant samples (Foto Contino).

A list was gathered of the herbs used in the Santeria in which there is correspondence between local names and scientific ones. Research was conducted on the correspondence between the traditional use and the scientifically recognized use of 39 species.

Results and Discussion

In Lydia Cabrera's work , 550 species of plants are described and characterized by a short description of uses, local name and, when present, Latin name.

We found that 255 scientific names are correct; for 38 species the taxonomic family is properly matched, but the Latin name is wrong (abey macho is identified like *Jacaranda jacaranda sangreana* instead of the right name *Jacaranda coerulea* (L.Griseb.). The scientific names transcribed with misspellings are 99 (for instance abrojo amarillo is transcribed *Tribulus cistides* instead of *Tribulus cistoides* Lin.), 33 species have a totally correct name, but for 125 plants it is totally absent (**Table 1**).

Many species have a mismatch between local name and scientific name. For instance, the herb commonly called anís, that in “*El Monte*” is identified as *Pimpinela asinum*, according to its medicinal uses, following investigations actually corresponds to *Anís Foeniculum vulgare*, that is traditionally called hinojo.

Another interesting point of the project is the correspondence between traditional medicinal uses and scientifically recognized uses. Very often there is a parallelism between the popular use and the effective presence of bioactive compounds is recognized by the pharmacopoeia, but sometimes the properties described by the traditions don't match the chemical and pharmacological studies.

Often, the lack of scientific evidences not necessarily suggests errors in the popular knowledge, but, instead, an insufficient scientific research to identify bioactive compounds responsible for the traditionally ascribed properties.

Of the 39 species that have been further studied from the medical point of view, 28 are subject of studies and have recognized medicinal properties.

Among these 28 species, only 6 show correspondence between the popular use and the properties.

A case is the banana tree (*Musa paradisiaca* L.), that is used by the local communities as a healing agent. Scientific studies demonstrated the presence in the plants of a vasoconstrictor substance useful in the regeneration of damaged or burnt tissues (Swanson, 2010).

Among the species that are found in the list, 5 have toxic characteristics, and are still traditionally used for healing and medicinal purposes.

Some examples are paraíso (*Melia azederach* Lin.) and añil (*Indigofera suffruticosa* Mill.). Cortex, leaves, fruit pulp, roots and oil extracted from seeds of paraíso are used in the Cuban tradition to treat tachycardia and dyspnea, as bactericidal and anti-pyretic. Recent studies proved, instead, the presence in the plant of tetra triterpen e and saponin, two powerful neurotoxins.

Añil is, in the traditional medicine, a disinfectant. It contains the compound Anilina, that turns out to be a toxic and carcinogenic compound for human beings.

A really widespread fruit in popular medicine is mango (*Mangifera indica* L.), used as anti-ulcerating, digestive, anti-parasitic and against asthma. Recently a research about the variety mango macho has shown the presence of mangiferin, which is believed to be a powerful anti-carcinogenic substance.

Conclusions

It is evident that ethnobotanical traditions in Cuba are still largely applied by the communities. The local people use herbs with medical purposes to treat themselves and their families. Their botanical knowledge is large and solid, but it is necessary to update and improve it, especially to eliminate the bad habit of using toxic or poisonous species.

Religious communities, very present in Cuba and in great increase in recent years, have wide empirical knowledge about the endemic vegetation and could contribute to research and identify useful species on which to focus new studies and scientific experiments.

New studies about the Cuban flora could be an opportunity to verify the medical properties of the species and possibly would find new useful bioactive compounds previously unknown.

The research conducted during this project allowed, in the first place, a complete review of local names according to the current systematics.

In the future this study could be favorable to identify botanical species used in the popular traditions and useful to religious practitioners of Santeria.

The project also provides a basis for future scientific investigations related to medical properties of the plants, which are used today in an empirical way and without sufficient scientific knowledge.

It will be possible, in the future, to focus research on some species, on which medical and analytical analyses can be performed.

From a general point of view, the project demonstrated the usefulness of preserving the traditional knowledge and the need to expand the connections between religious communities and the scientific world.

Science, in fact, could benefit from their empirical knowledge and could find integrations with them.

To conclude, the exchange of knowledge between scientists and empirical experts could be beneficial for both parties.
