

Name _____

Period _____

“Good Buddies” ProjectWILD Activity

Elements of any ecological system live in an intricate web of interdependence. When two species of organisms live in close association with each other, their relationship is called “symbiotic.” In a symbiotic relationship, at least one of the organisms directly benefits from its close association with the other organism. There are three major forms of symbiotic relationships: commensalisms, mutualism, and parasitism.

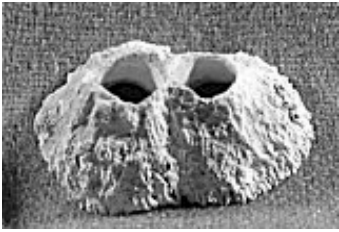

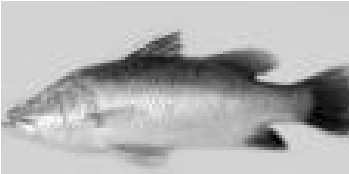

Define the following terms:

1. Commensalism – _____
2. Mutualism – _____
3. Parasitism – _____

Procedure:

- Working in pairs, decide who each organism forms a symbiotic relationship with. You will need to **cut** and **paste** the **matching organisms** and **descriptions** into the given chart. Then, identify the **type of symbiotic relationship** it is by **circling** the correct answer.
- You will want to CHECK YOUR ANSWERS with me before pasting!!!!

ORGANISM	MATCHING ORGANISM	DESCRIPTION	RELATIONSHIP
GAZELLE 			Commensalism Mutualism Parasitism
CUCKOO 			Commensalism Mutualism Parasitism
YUCCA 			Commensalism Mutualism Parasitism

As Species A walks through grass, insects become active and are seen and eaten by Species B .	Species A alerts and directs Species B to bee hives. Species B then exposes the hives and feeds on the honey first. Next Species A eats the honey.	Species A feeds on the parasites found on Species B's body.
Species A extracts water and nutrients from Species B to Species B's detriment.	Species A feeds on Species B's blood to Species B's detriment.	Species A uses its saw-like bill to cut up the dead animals it eats. As a result, the dead animal carcass is accessible to Species B for food and egg laying.
Species A lives and hunt with Species B , and both have access to the prey.	Species A attach themselves to Species B's body. They then travel with Species B and feed on leftover food scraps from Species B's meal.	Species A and Species B feed next to each other. They both watch for predators and alert each other to danger. They each see predators the other wouldn't see.
Species A lives in a specific body part of Species B that Species B has abandoned.	Species A creates home sites by attaching itself to Species B .	Species A feeds on Species B's blood to Species B's detriment.
Species A feeds on the ticks found on Species B .	Species A may lay its eggs in Species B's nest. Species A's young will displace Species B's young, and Species B will raise Species A's young.	Species A is pollinated by Species B . Species B lay their eggs in the flowers where larvae hatch and eat some of the developing seeds.
