Current Research: Stress and the Cortical GABAergic system

Sixty percent of the human brain and a large part of all mammals' brain is constituted by the cortical mantle, which elaborates sensory information, and uses it to coordinate motor activity and behavior according to the biological, metabolic, and cognitive needs of the animal. Neurons releasing the amino acid GABA (**GABAergic**) are a large class of cortical **cells** comprising of **4-20% of cortical neurons**, which in the adult individual are typically inhibitory, **whose malfunction is associated with numerous neurological and psychiatric conditions**. **Because of their biochemical and morphological properties, GABAergic neurons are particularly vulnerable to physical, chemical, and psychological stress**, increasing the risk –in genetically predisposed individuals- for the occurrence of neurological and psychiatric conditions including epilepsy, psychoses, attention deficit disorders, schizophrenic psychoses, as well as of disorders in the anxiety and in the autistic spectrums. **Our laboratory is fully equipped to carry out in vitro electrophysiology (2 patch-clamp set up systems) as well as rodent behavioral tests.**

We are interested in determining the role and molecular nature of the interaction between stress and the GABAergic system in the pathophysiology of neuropsychiatric conditions. We pursue this aim using **electrophysiological, pharmacological, and behavioral techniques in animal models, mainly rat and mouse**. In the last years we extensively studied the way in which monoamine and catecholamines –particularly norepinephrine- **modulate cortical synaptic network**, particularly in the **temporal and prefrontal cortices**. Our current focus is on the prefrontal cortex, on the molecular nature of the pathophysiology of the GABAergic system, and on the development of possible therapeutic means to recover stress-induced loss-of-function of the GABAergic system. Our present projects use genetically modified mouse models to **evaluate the consequence of stress-induced elevation in the levels of pro-inflammatory cytokines as alterations in the local balance between synaptic inhibition/excitation**.

Hon. Research Assistant

Past research

- Electrophysiology and morphology of the GABAergic system of the hippocampus.
- Neuropeptide and monoamine modulation of GABAergic synaptic transmission.
- Dynamics and properties of cortical glutamatergic synaptic transmission
- Voltage gated K⁺ channels
- Physiology of auditory receptors
- Role of acetylcholine and monoamines in the temporal cortex
- Action of monoamines and cholinomimetics on auditory attention
- Effects of monoamines and cholinomimetics on attention
- Monoamine and acetylcholine direct modulation of NMDA receptors

Animal models and clinical applications

- Auditory rehabilitation
- Attention Deficit Disorders
- Autistic Spectrum Disorders
- Epilepsy
- Schizophrenia
- Psychoses
- Disorders of the Anxiety Spectrum
- Lipopolisaccharide-induced inflammation (aseptic inflammation)
- Vagal Nerve Stimulation (VNS)

Laboratory techniques

Slice Physiology:

patch-clamp, sharp electrodes and extracellular recording in rodent brain slices

In-vivo physiology:

Multi-single-unit extracellular recording, topical iontophoresis and pressure drug application, intraventricular drug injections, Stimulation of the Vagal Nerve (VNS)

Anatomy and Immunohistochemistry:

biocytin single-cell reconstruction - neuron tracing, proteins monitoring with fluorescence techniques

Behavior:

PC-based automated measurement of auditory attention in operating chambers, open field, Y maze, plus maze, rodent enriched environment,

Stress protocols:

Lipopolysaccharide injection, Mild electric shock, Restraint Stress, Prenatal Valproic Acid injections, Pentylenetetrazole-induced convulsions, Social stress (CD1-induced)
